How to Deploy Redis Cluster on Kubernetes

September 30, 2021

KUBERNETES REDIS

[Home](#) » [DevOps and Development](#) » How to Deploy Redis Cluster on Kubernetes

Introduction

Redis is a popular [NoSQL database](#) and an in-memory [data store](#) supporting multiple abstract data structures. These include strings, lists, hashes, sets, streams, etc. Redis provides syntax for accessing mutable data structures, allowing multiple processes to read and write them in a shared way.

A Redis Cluster is a set of Redis instances that automatically shards data across nodes. Using a cluster gives users the ability to split their datasets among nodes and keep running the database even when some nodes fail.

This tutorial will show you how to deploy a Redis Cluster on Kubernetes using ConfigMap and Helm.

How to Deploy Redis Cluster on Kubernetes

Prerequisites

- [A Kubernetes cluster](#) consisting of two or more nodes
- [Helm 3 installed](#)
- kubectl 1.14 or above installed

Note: If you are using Minikube, you can simulate a two-node cluster by adding the `--nodes` option to the `start` command:

```
minikube start --nodes 2
```

Deploying Redis on Kubernetes with ConfigMap

The following steps explain how to configure Redis cache and a pod containing a Redis instance.

1. Using a text editor, [create a ConfigMap](#) YAML that will store the Redis configuration.

```
nano redis-conf.yaml
```

VALENTINE'S DAY SPECIAL: Up to 33% OFF selected dedicated servers and components!

GET COUPON CODE

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: test-redis-config
data:
  redis-config: |
    maxmemory 2mb
    maxmemory-policy allkeys-lru
```

The example configuration above sets the **maxmemory** directive and tells Redis to use the maximum of 2 MB of storage for the data set. The **maxmemory-policy** directive defines the procedure to be applied when the memory limit is reached. **allkeys-lru** first removes the less recently used (LRU) keys.

3. Save the file and exit.
4. Create the ConfigMap by applying the YAML file.

```
kubectl apply -f redis-conf.yaml
```

The system confirms that the operation was successful.

```
marko@test-main:~/redis$ kubectl apply -f redis-conf.yaml
configmap/test-redis-config created
marko@test-main:~/redis$
```

5. Create a Redis pod manifest.

```
nano redis-pod.yaml
```

6. Specify your pod configuration.

VALENTINE'S DAY SPECIAL: Up to 33% OFF selected dedicated servers and components!

GET COUPON CODE

```
name: redis
spec:
  containers:
  - name: redis
    image: redis:5.0.4
    command:
    - redis-server
    - "/redis-master/redis.conf"
    env:
    - name: MASTER
      value: "true"
    ports:
    - containerPort: 6379
    resources:
      limits:
        cpu: "0.1"
    volumeMounts:
    - mountPath: /redis-master-data
      name: data
    - mountPath: /redis-master
      name: config
  volumes:
  - name: data
    emptyDir: {}
  - name: config
    configMap:
      name: test-redis-config
      items:
      - key: redis-config
        path: redis.conf
```

In the example above, the manifest defines **config** volume and mounts it at **/redis-master** directory on the pod. The **spec.volumes.items** section then exposes the **redis-config** key

VALENTINE'S DAY SPECIAL: Up to 33% OFF selected dedicated servers and components!

GET COUPON CODE

```
kubectl apply -f redis-pod.yaml
```

The system confirms that the pod creation was successful.

```
marko@test-main:~/redis$ kubectl apply -f redis-pod.yaml
pod/redis created
marko@test-main:~/redis$
```

9. Check pod status.

```
kubectl get pod
```

```
marko@test-main:~/redis$ kubectl get pods
NAME      READY   STATUS    RESTARTS   AGE
redis     1/1     Running   0           2m7s
marko@test-main:~/redis$
```

10. Enter the created pod with `kubectl exec`.

```
kubectl exec -it redis -- redis-cli
```

The Redis server console appears:

```
marko@test-main:~/redis$ kubectl exec -it redis -- redis-cli
127.0.0.1:6379>
```

11. Use the [PING command](#) to check if the server is online.

```
PING
```

```
127.0.0.1:6379> PING
PONG
127.0.0.1:6379>
```

maximum performance of your Redis cluster. Achieve a reliable infrastructure with servers starting at **only \$0.10/hour!**

Deploying Redis on Kubernetes with Helm Chart

Helm provides a quick way of setting up a Redis cluster using a pre-made [Helm chart](#).

1. [Add the Helm repository](#) containing the Redis chart you wish to install.

```
helm repo add [repo-name] [repo-address]
```

This article uses the Redis chart available in the Bitnami repository.

```
marko@test-main:~/redis$ helm repo add bitnami https://charts.bitnami.com/bitnami
"bitnami" has been added to your repositories
marko@test-main:~/redis$
```

2. Update local Helm repositories.

```
helm repo update
```

```
marko@test-main:~/redis$ helm repo update
Hang tight while we grab the latest from your chart repositories...
...Successfully got an update from the "kubernetes-dashboard" chart repository
...Successfully got an update from the "banzaicloud-stable" chart repository
...Successfully got an update from the "stable" chart repository
...Successfully got an update from the "bitnami" chart repository
Update Complete. ☺Happy Helming!☺
marko@test-main:~/redis$
```

3. Use `helm install` to install the chart. The basic command is as follows:

```
helm install redis-test bitnami/redis
```

VALENTINE'S DAY SPECIAL: Up to 33% OFF selected dedicated servers and components!

GET COUPON CODE

`fs-client` for both pods.

Since Redis is deployed with non-administrative volume permissions by default, the Redis pod may not be able to communicate with the server. Resolve this problem by setting **volumePermissions** to **true**.

The final `helm install` command should look like this:

```
helm install redis-test --set persistence.storageClass=nfs-client,redis.replicas.persistence.storageClass=nfs-client bitnami/redis --set volumePermissions.enabled=true
```

4. Export the Redis password as an [environment variable](#).

```
export REDIS_PASSWORD=$(kubectl get secret --namespace default redis-test -o jsonpath="{.data.redis-password}" | base64 --decode)
```

5. Create a Redis client pod that you will use to access the database.

```
kubectl run --namespace default redis-client --restart='Never' --env REDIS_PASSWORD=$REDIS_PASSWORD --image docker.io/bitnami/redis:6.2.5-debian-10-r63 --command -- sleep infinity
```

The system confirms the creation of the **redis-client** pod.

VALENTINE'S DAY SPECIAL: Up to 33% OFF selected dedicated servers and components!

GET COUPON CODE

```
kubectl exec --tty -i redis-client --namespace default -- bash
```

The client console appears.

7. Use the following **redis-cli** command to access the Redis master instance:

```
redis-cli -h redis-test-master -a $REDIS_PASSWORD
```

The console for the master instance displays.

8. To access the replicas, use the same command, but alter the target.

```
redis-cli -h redis-test-replicas -a $REDIS_PASSWORD
```

9. Use the **PING** command to test the connection with the server.

```
PING
```

The **PONG** response confirms that the server is listening.
